Outline

- Value iteration recap
- Learning from trajectories
 - MC approach
 - Temporal difference
- Q-learning
- Exploration-exploitation tradeoff
- SARSA
- Experience replay
- Practice

Previously...

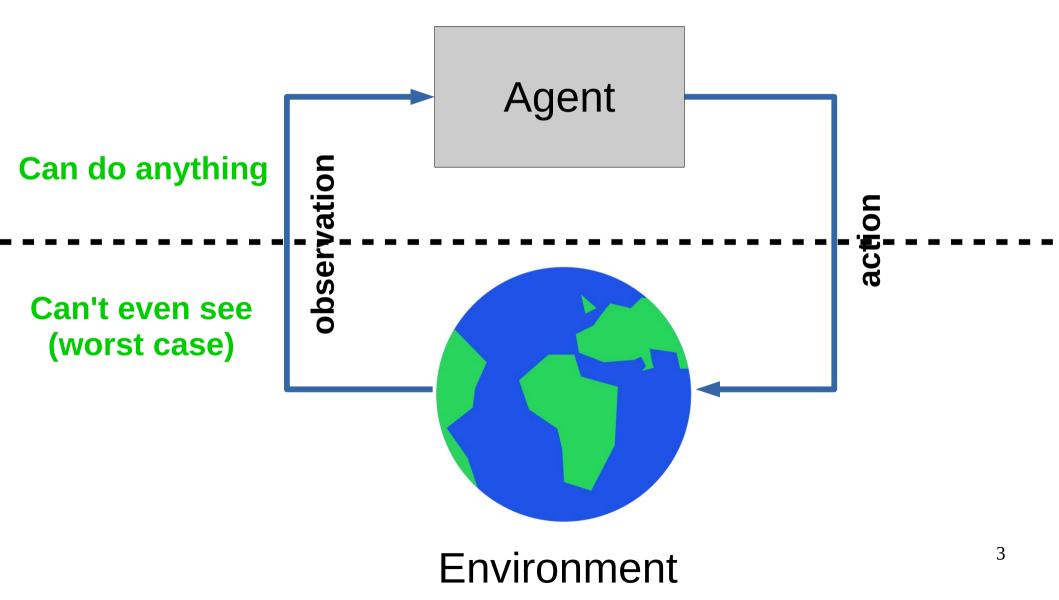

V(s) and V*(s,a)

know V* and P(s'|s,a) → know optimal policy

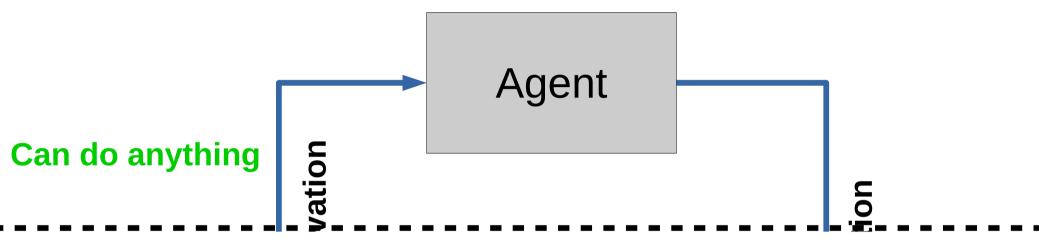

We can learn V* with dynamic programming

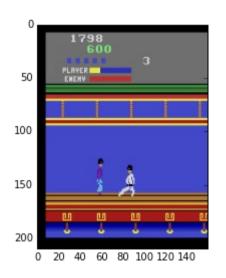

$$V_{i+1}(s) := \max_{a} [r(s,a) + \gamma \cdot E_{s' \sim P(s'|s,a)} V_i(s')]$$

Decision process in the wild

Decision process in the wild

Model-free setting:

We don't know actual P(s',r|s,a)

Whachagonnado?

Model-free setting:

We don't know actual P(s',r|s,a)

Learn it?
Get rid of it?

More new letters

- $V_{\pi}(s)$ expected G from state s if you follow π
- $V^*(s)$ expected G from state s if you follow π^*

More new letters

- $V_{\pi}(s)$ expected G from state s if you follow π
- $V^*(s)$ expected G from state s if you follow π^*

- $Q_{\pi}(s,a)$ expected G from state s
 - if you start by taking action a
 - and follow π from next state on

• **Q*(s,a)** – guess what it is :)

More new letters

- $V_{\pi}(s)$ expected G from state s if you follow π
- $V^*(s)$ expected G from state s if you follow π^*

- $Q_{\pi}(s,a)$ expected G from state s
 - if you start by taking action a
 - and follow π from next state on

• $Q^*(s,a)$ – same as $Q_{\pi}(s,a)$ where $\pi = \pi^*$

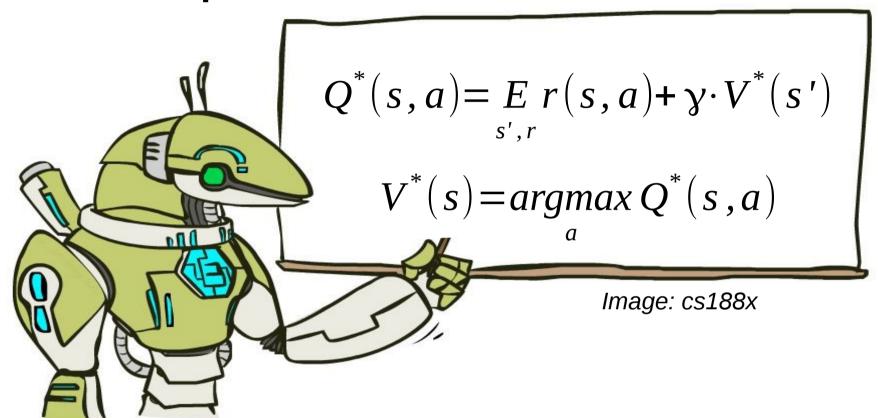

Trivia

- Assuming you know Q*(s,a),
 - how do you compute π*

- how do you compute V*(s)?

- Assuming you know V(s)
 - how do you compute Q(s,a)?

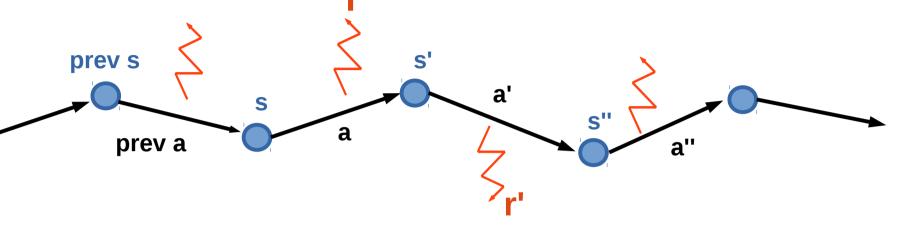

To sum up

Action value $Q_{\pi}(s,a)$ is the expected total reward G agent gets from state s by taking action a and following policy π from next state.

$$\pi(s)$$
: $argmax_a Q(s,a)$

Learning from trajectories

Model-based: you know P(s'|s,a)

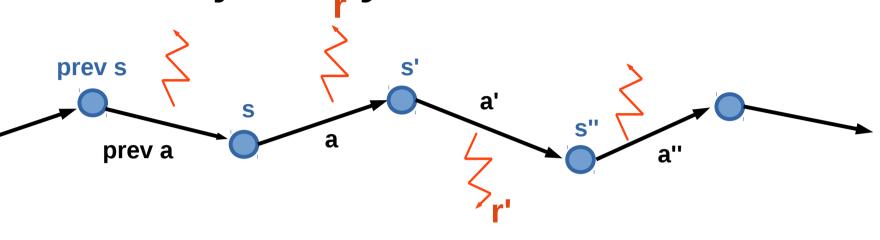

- can apply dynamic programming
- can plan ahead

Model-free: you can sample trajectories

- can try stuff out
- insurance not included

- Trajectory is a sequence of
 - states (s)
 - actions (a)
 - rewards (r)
- We can only sample trajectories

MDP trajectory

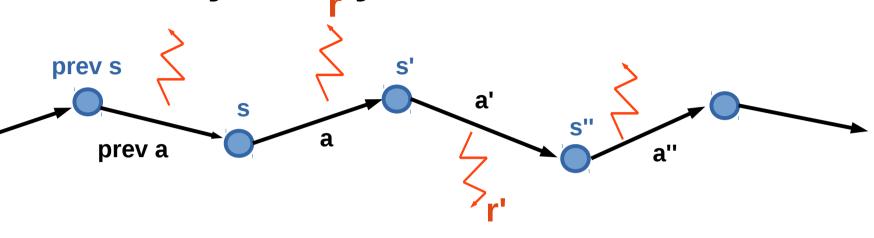

- Trajectory is a sequence of
 - states (s)
 - actions (a)
 - rewards (r)

Q: What to learn? V(s) or Q(s,a)

We can only sample trajectories

MDP trajectory

- Trajectory is a sequence of
 - states (s)
 - actions (a)
 - rewards (r)

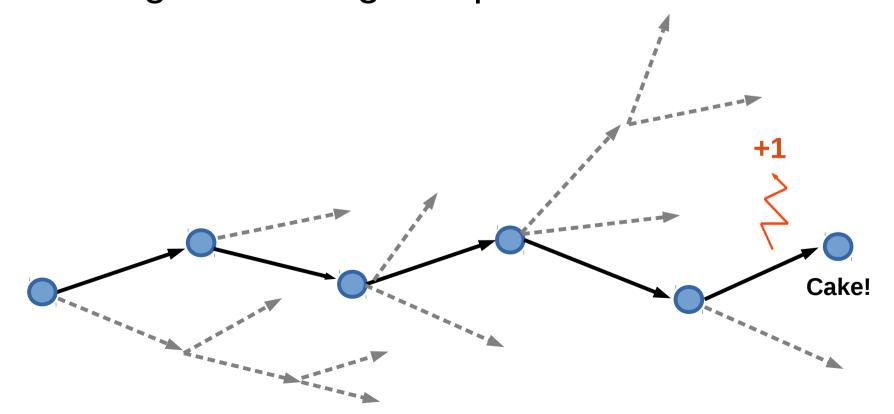

Q: What to learn? V(s) or Q(s,a)

V(s) is useless without P(s'|s,a)

We can only sample trajectories

Idea 1: monte-carlo

- Get all trajectories containing particular (s,a)
- Estimate G(s,a) for each trajectory
- Average them to get expectation

Idea 1: monte-carlo

- Get all trajectories containing particular (s,a)
- Estimate G(s,a) for each trajectory
- Average them to get expectation

takes a lot of sessions

Image: super meat boy

Remember we can improve Q(s,a) iteratively!

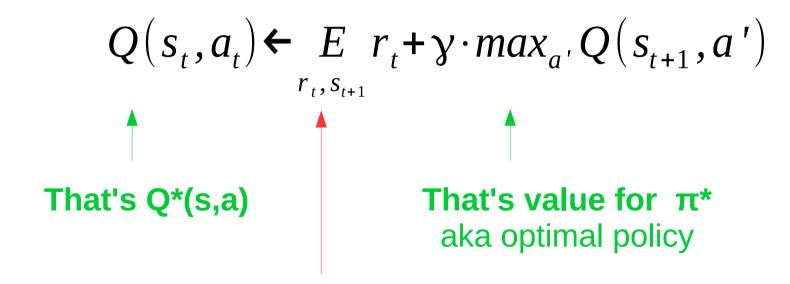

$$Q(s_t, a_t) \leftarrow E_{r_t, s_{t+1}} r_t + \gamma \cdot max_{a'} Q(s_{t+1}, a')$$

Remember we can improve Q(s,a) iteratively!

$$Q(s_t, a_t) \leftarrow E r_t + \gamma \cdot max_{a'} Q(s_{t+1}, a')$$

$$\uparrow \qquad \qquad \uparrow$$
That's Q*(s,a)
That's value for π^* aka optimal policy

Remember we can improve Q(s,a) iteratively!

That's something we don't have

What do we do?

Replace expectation with sampling

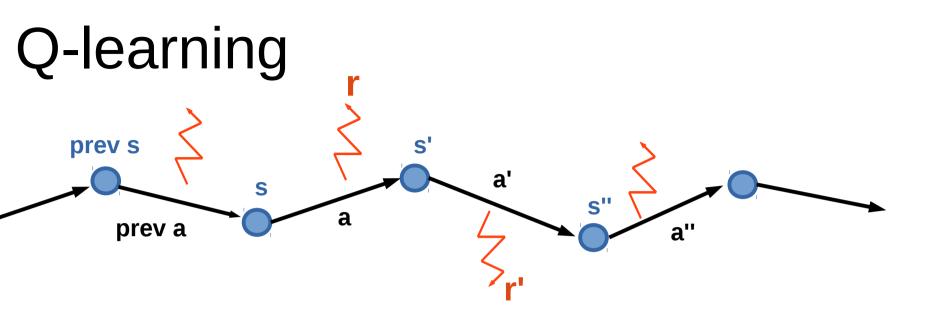

$$E_{r_t,s_{t+1}} r_t + \gamma \cdot \max_{a'} Q(s_{t+1},a') \approx \frac{1}{N} \sum_{i} r_i + \gamma \cdot \max_{a'} Q(s_i^{next},a')$$

Replace expectation with sampling

$$E_{r_t,s_{t+1}} r_t + \gamma \cdot \max_{a'} Q(s_{t+1},a') \approx \frac{1}{N} \sum_{i} r_i + \gamma \cdot \max_{a'} Q(s_i^{next},a')$$

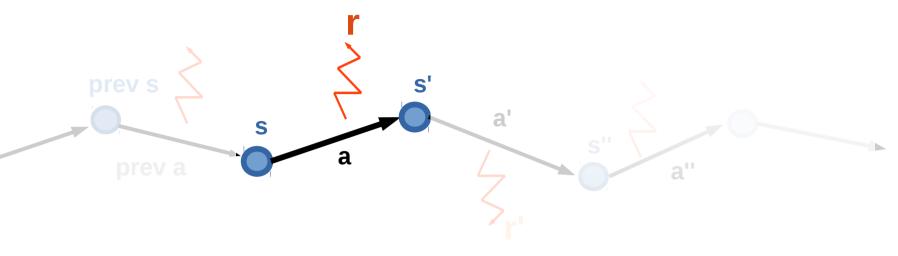

Use moving average with just one sample!

$$Q(s_t, a_t) \leftarrow \alpha \cdot (r_t + \gamma \cdot max_{a'} Q(s_{t+1}, a')) + (1 - \alpha) Q(s_t, a_t)$$

- Works on a sequence of
 - states (s)
 - actions (a)
 - rewards (r)

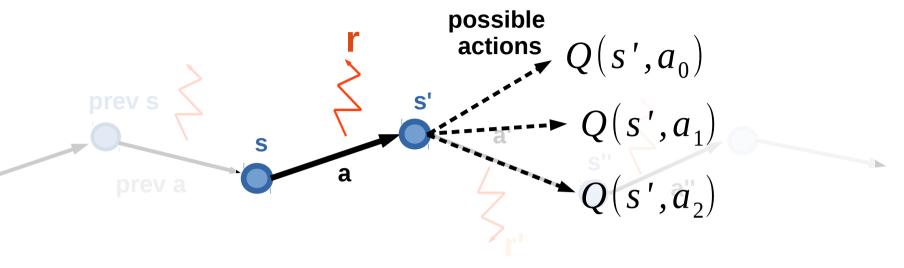

Q-learning

Initialize Q(s,a) with zeros

- Loop:
 - Sample <s,a,r,s'> from env

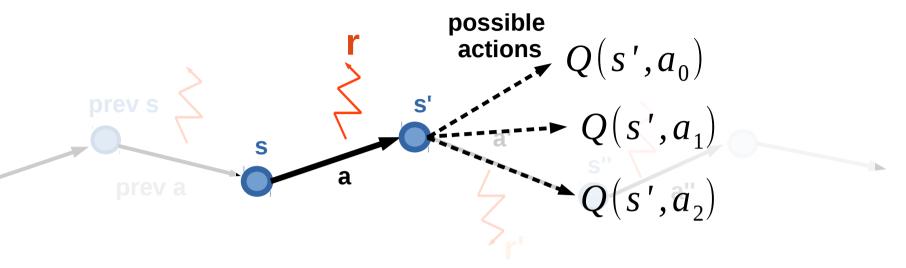

Q-learning

Initialize Q(s,a) with zeros

- Loop:
 - Sample <**s**,**a**,**r**,**s**'> from env
 - Compute $\hat{Q}(s,a)=r(s,a)+\gamma \max_{a_i} Q(s',a_i)$

Q-learning

Initialize Q(s,a) with zeros

- Loop:
 - Sample <s,a,r,s'> from env
 - Compute $\hat{Q}(s,a)=r(s,a)+\gamma \max_{a_i} Q(s',a_i)$
 - Update $Q(s,a) \leftarrow \alpha \cdot \hat{Q}(s,a) + (1-\alpha)Q(s,a)$

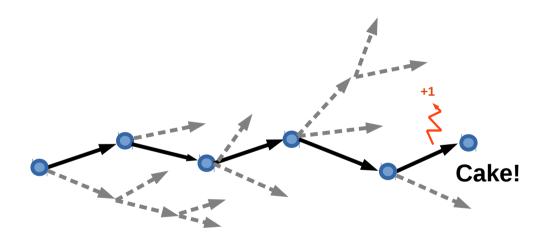

Recap

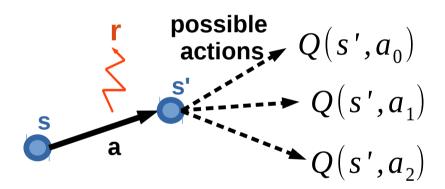

Monte-carlo

Averages Q over sampled paths

Temporal Difference

Uses recurrent formula for Q

Nuts and bolts: MC vs TD

Monte-carlo

- Averages Q over sampled paths
- Needs full trajectory to learn
- Less reliant on markov property

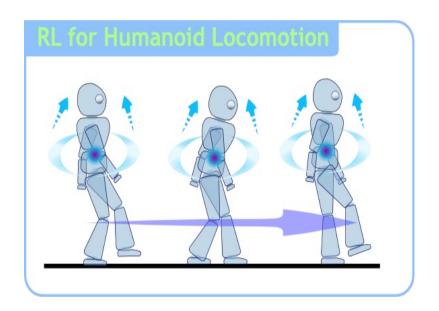

Temporal Difference

- Uses recurrent formula for Q
- Learns from partial trajectory
 Works with infinite MDP
- Needs less experience to learn

What could possibly go wrong?

Our mobile robot learns to walk.

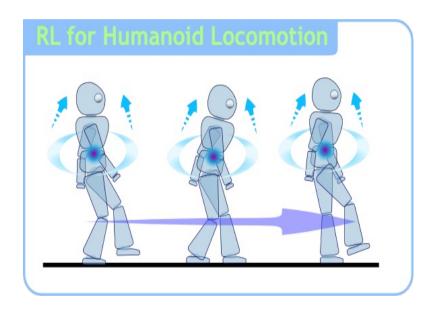

Initial Q(s,a) are zeros robot uses argmax Q(s,a)

He has just learned to crawl with positive reward! 30

What could possibly go wrong?

Our mobile robot learns to walk.

Initial Q(s,a) are zeros robot uses argmax Q(s,a)

Too bad, now he will never learn to walk upright $= \mathcal{E}^1$

What could possibly go wrong?

New problem:

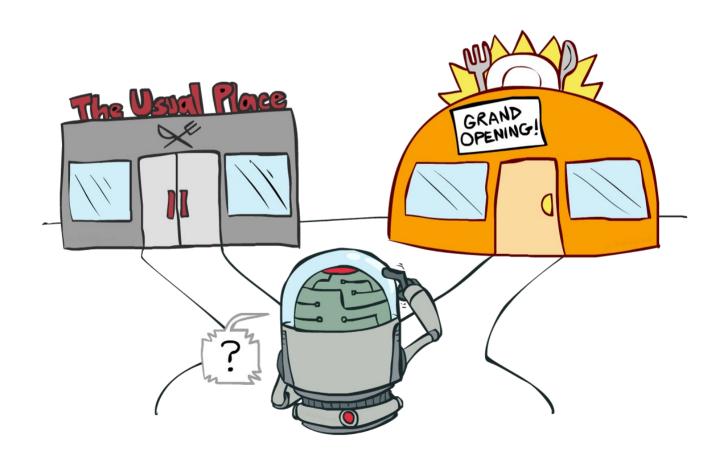

If our agent always takes "best" actions from his current point of view,

How will he ever learn that other actions may be better than his current best one?

Ideas?

Exploration Vs Exploitation

Balance between using what you learned and trying to find something even better

Exploration Vs Exploitation

Strategies:

- · ε-greedy
 - · With probability ε take random action; otherwise take optimal action.

Exploration Vs Exploitation

Strategies:

- · ε-greedy
 - · With probability ε take random action; otherwise take optimal action.
- · Softmax

Pick action proportional to softmax of shifted normalized Q-values.

$$\pi(a|s) = softmax(\frac{Q(s,a)}{\tau})$$

More cool stuff coming later

Exploration over time

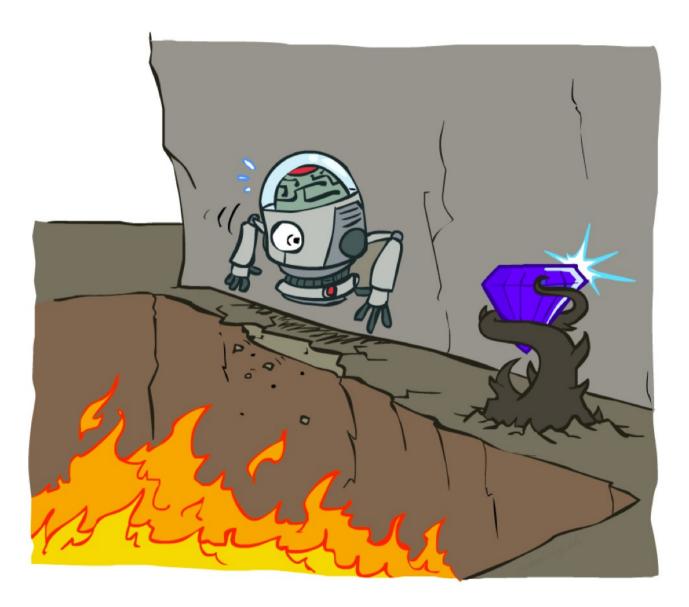

Idea:

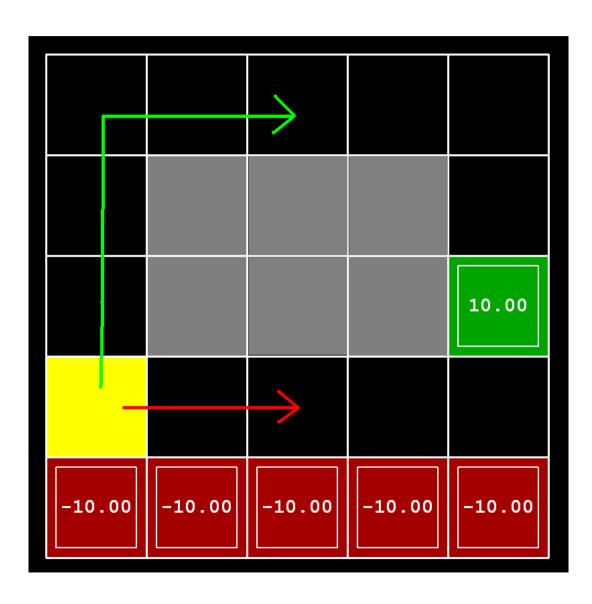

If you want to converge to optimal policy, you need to gradually reduce exploration

Example:

Initialize ε -greedy ε = 0.5, then gradually reduce it

- If $\epsilon \to 0$, it's greedy in the limit
- · Be careful with non-stationary environments

Conditions

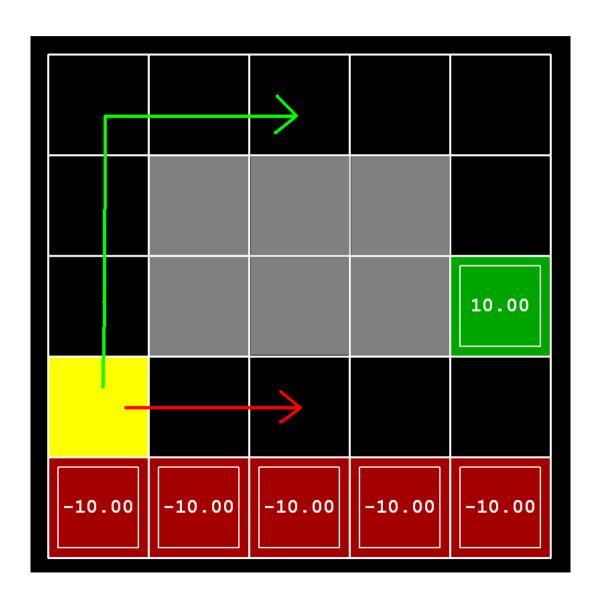

· Q-learning

$$\gamma = 0.99 \ \epsilon = 0.1$$

· no slipping

Trivia:

What will q-learning learn?

Conditions

· Q-learning

$$\gamma = 0.99 \ \epsilon = 0.1$$

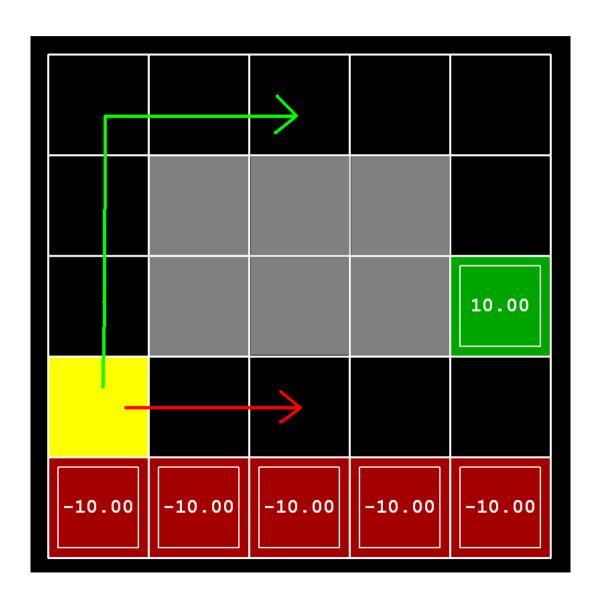

no slipping

Trivia:

What will q-learning learn?

follow the short path

Will it maximize reward?

Conditions

· Q-learning

$$\gamma = 0.99 \ \epsilon = 0.1$$

no slipping

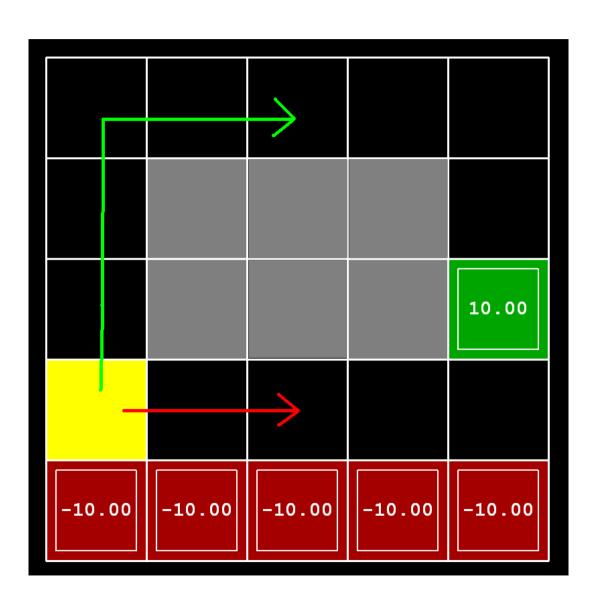

Trivia:

What will q-learning learn?

follow the short path

Will it maximize reward?

no, robot will fall due to epsilon-greedy "exploration"

Conditions

· Q-learning

$$\gamma = 0.99 \ \epsilon = 0.1$$

no slipping

Decisions must account for actual policy!

e.g. ε-greedy policy

Generalized update rule

Update rule (from Bellman eq.)

$$Q(s_t, a_t) \leftarrow \alpha \cdot \hat{Q}(s_t, a_t) + (1 - \alpha)Q(s_t, a_t)$$
"better Q(s,a)"

Q-learning VS SARSA

Update rule (from Bellman eq.)

$$Q(s_t, a_t) \leftarrow \alpha \cdot \hat{Q}(s_t, a_t) + (1 - \alpha)Q(s_t, a_t)$$

Q-learning

$$\hat{Q}(s,a) = r(s,a) + \gamma \cdot \max_{a'} Q(s',a')$$

Q-learning VS SARSA

Update rule (from Bellman eq.)

$$Q(s_t, a_t) \leftarrow \alpha \cdot \hat{Q}(s_t, a_t) + (1 - \alpha)Q(s_t, a_t)$$

Q-learning

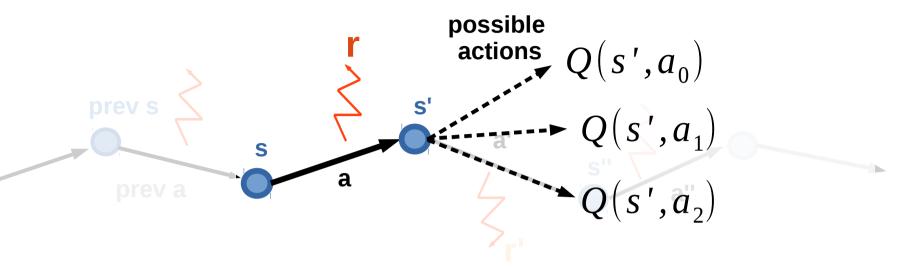

"better Q(s,a)"

$$\hat{Q}(s,a) = r(s,a) + \gamma \cdot \max_{a'} Q(s',a')$$

SARSA

$$\hat{Q}(s,a) = r(s,a) + \gamma \cdot E_{a' \sim \pi(a'|s')} Q(s',a')$$

Recap: Q-learning

$$\forall s \in S, \forall a \in A, Q(s,a) \leftarrow 0$$

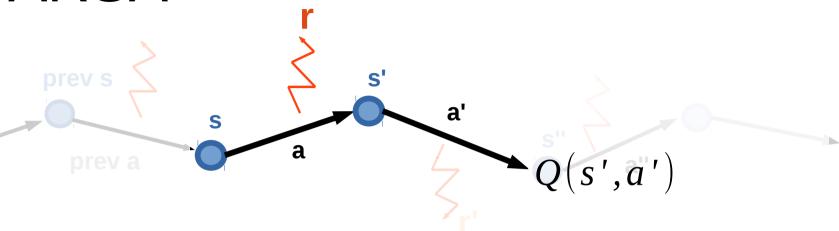

Loop:

Sample <s,a,r,s'> from env

- Compute
$$\hat{Q}(s,a)=r(s,a)+\gamma \max_{a_i} Q(s',a_i)$$

- Update
$$Q(s,a) \leftarrow \alpha \cdot \hat{Q}(s,a) + (1-\alpha)Q(s,a)$$

SARSA

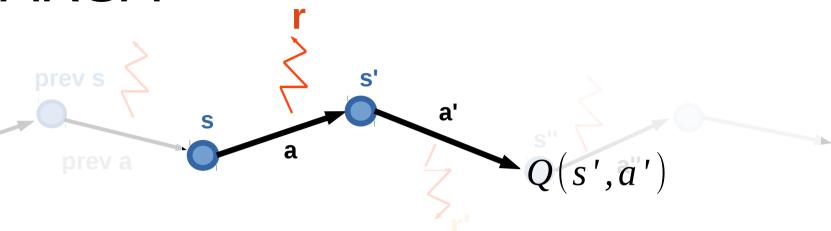

$$\forall s \in S, \forall a \in A, Q(s,a) \leftarrow 0$$

Loop:

- Sample <s,a,r,s',a'> from env
- Compute $\hat{Q}(s,a)=r(s,a)+\gamma Q(s',a')$
- Update $Q(s,a) \leftarrow \alpha \cdot \hat{Q}(s,a) + (1-\alpha)Q(s,a)$

SARSA

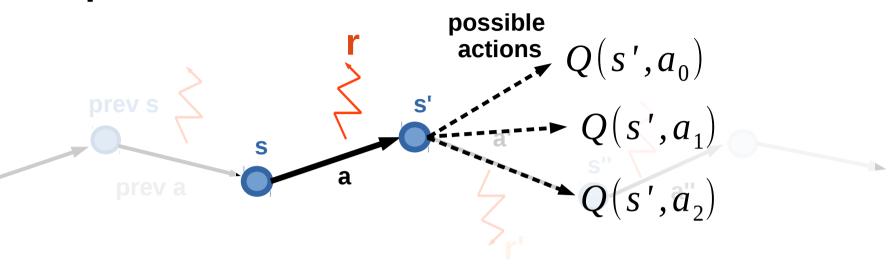

$$\forall s \in S, \forall a \in A, Q(s,a) \leftarrow 0$$

Loop:

hence "SARSA"

- Sample <s,a,r,s',a'> from env
- Compute $\hat{Q}(s,a)=r(s,a)+\gamma Q(s',a')$ next action (not max)
- Update $Q(s,a) \leftarrow \alpha \cdot \hat{Q}(s,a) + (1-\alpha)Q(s,a)$

Expected value SARSA

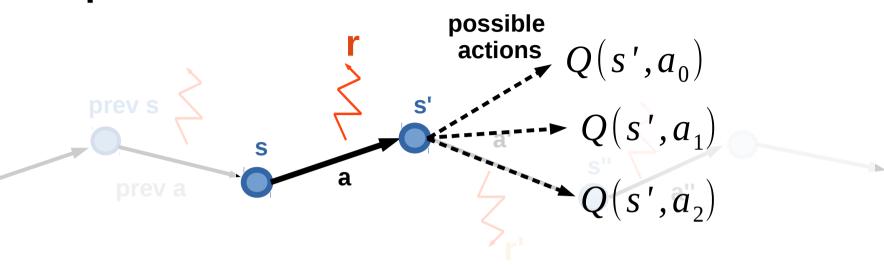

$$\forall s \in S, \forall a \in A, Q(s,a) \leftarrow 0$$

Loop:

- Sample <s,a,r,s'> from env
- Compute $\hat{Q}(s,a)=r(s,a)+\gamma \mathop{E}_{a_i\sim\pi(a|s')}Q(s',a_i)$
- Update $Q(s,a) \leftarrow \alpha \cdot \hat{Q}(s,a) + (1-\alpha)Q(s,a)$

Expected value SARSA

$$\forall s \in S, \forall a \in A, Q(s,a) \leftarrow 0$$

Loop:

Sample <s,a,r,s'> from env

Expected value

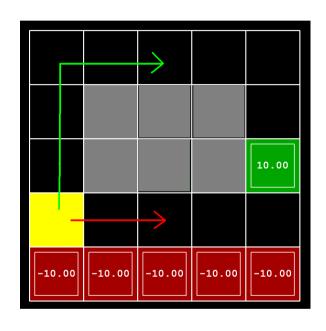

- Compute
$$\hat{Q}(s,a)=r(s,a)+\gamma \mathop{E}_{a_i\sim\pi(a|s')} Q(s',a_i)$$

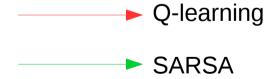

- Update
$$Q(s,a) \leftarrow \alpha \cdot \hat{Q}(s,a) + (1-\alpha)Q(s,a)$$

Difference

 SARSA gets optimal rewards under current policy

 Q-learning policy would be optimal under

Two problem setups

on-policy

off-policy

Agent **can** pick actions

- Most obvious setup :)
- Agent always follows his own policy

- Learning with exploration,
 playing without exploration
- Learning from expert (expert is imperfect)
- Learning from sessions (recorded data)

Two problem setups

on-policy

off-policy

Agent can pick actions

Agent can't pick actions

On-policy algorithms can't learn off-policy

Off-policy algorithms can learn on-policy

learn optimal policy even if agent takes random actions

Q: which of Q-learning, SARSA and exp. val. SARSA will **only** work on-policy?

Two problem setups

on-policy

off-policy

Agent can pick actions

- On-policy algorithms can't learn off-policy
- SARSA
- more later

- Off-policy algorithms can learn on-policy
- Q-learning
- Expected Value SARSA

Two problem setups

on-policy

off-policy

Agent **can** pick actions

- On-policy algorithms can't learn off-policy
- SARSA
- more coming soon

- Off-policy algorithms can learn on-policy
- Q-learning
- Expected Value SARSA

Two problem setups

on-policy

off-policy

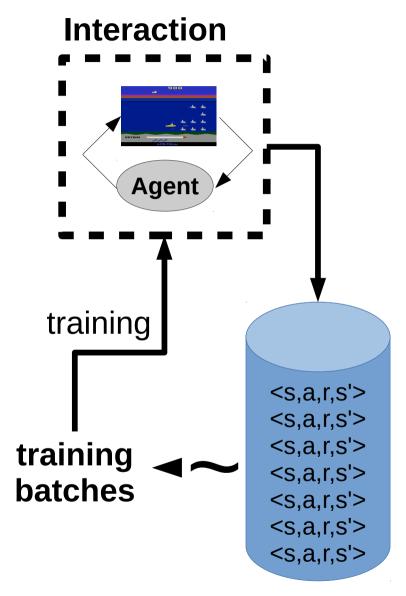

Agent **can** pick actions

- On-policy algorithms can't learn off-policy
- SARSA
- more coming soon

- Off-policy algorithms can learn on-policy
- Q-learning
- Expected Value SARSA

Experience replay

Idea: store several past interactions <s,a,r,s'>
Train on random subsamples

Replay buffer

Experience replay

Idea: store several past interactions <s,a,r,s'>
Train on random subsamples

Training curriculum:

- play 1 step and record it
- pick N random transitions to train

Profit: you don't need to re-visit same (s,a) many times to learn it.

Interaction **Agent** training <s,a,r,s'> <s,a,r,s'> <s,a,r,s'> training <s,a,r,s'> batches <s,a,r,s'> <s,a,r,s'> <s,a,r,s'>

Only works with off-policy algorithms!

Btw, why only them?

Replay buffer

Experience replay

Idea: store several past interactions <s,a,r,s'>
Train on random subsamples

Training curriculum:

- play 1 step and record it
- pick N random transitions to train

Profit: you don't need to re-visit same (s,a) many times to learn it.

Only works with off-policy algorithms!

Old (s,a,r,s) are from older/weaker version of policy!

</chapter> Interaction **Agent** training <s,a,r,s'> <s,a,r,s'> <s,a,r,s'> training <s,a,r,s'> batches <s,a,r,s'> <s,a,r,s'> <s,a,r,s'>

Replay buffer

New stuff we learned

• Anything?

New stuff we learned

• Q(s,a),Q*(s,a)

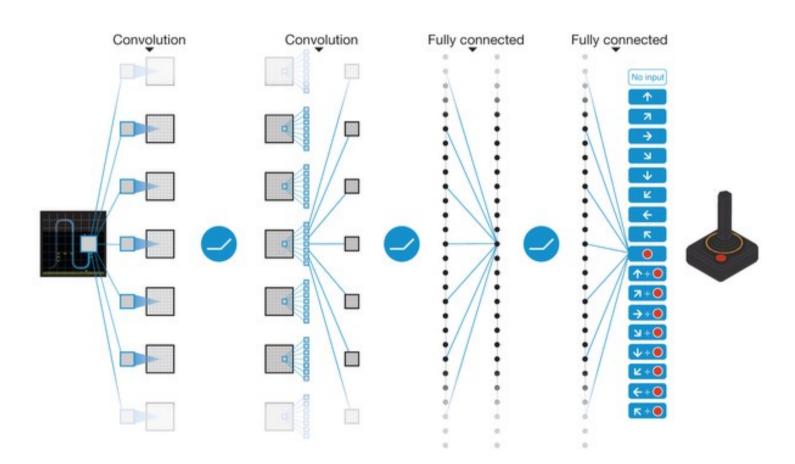

- Q-learning, SARSA
 - We can learn from trajectories (model-free)

Exploration vs exploitation (basics)

- Learning On-policy vs Off-policy
 - Using experience replay

Coming next...

- What if state space is large/continuous
 - Deep reinforcement learning

Outro and Q & A

- Remember what Q(s, a) and V(s) functions do
- Remember both about exploration and exploitation
 - At least using greedy policy or softmax smoothing
- Remember the difference between on-policy and off-policy algorithms!
 - On-policy algorithms can't learn off-policy (e.g. SARSA)
 - Off-policy algorithms can learn on-policy (e.g. Q-learning)
- Experience replay: no need to re-visit same (s,a) many times to learn it.
 - Works only with off-policy algorithms
